Internet routing

V. Arun

CS491G: Computer Networking Lab University of Massachusetts Amherst

Graph abstraction

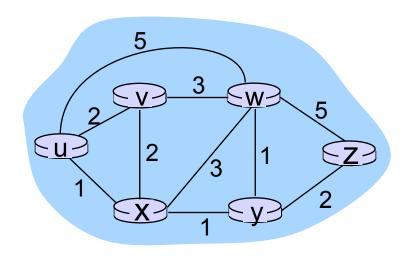

graph: G = (N,E)

 $N = set of routers = \{ u, v, w, x, y, z \}$

 $E = \text{set of links} = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

Graph abstraction: costs

$$c(x,x') = cost of link (x,x')$$

e.g., $c(w,z) = 5$

cost could always be 1, or inversely related to bandwidth, or related to congestion

cost of path
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

key question: what is the least-cost path between u and z? routing algorithm: algorithm that finds that least cost path

Routing algorithm classification

Q: global or decentralized information?

global:

- all routers have complete topology, link cost info
- "link state" algorithms decentralized:
- router knows physicallyconnected neighbors, link costs to neighbors
- iterative process of computation, exchange of info with neighbors
- "distance vector" algorithms

Q: static or dynamic?

static:

routes change slowly over time

dynamic:

- routes change more quickly
 - periodic update
 - in response to link cost changes

4. Internet Routing: Outline

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP

A Link-State Routing Algorithm

Dijkstra's algorithm

- net topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- computes least cost paths from one node ('source'') to all other nodes
 - gives forwarding table for that node
- iterative: after k
 iterations, know least cost
 path to k dest.'s

notation:

- **\star** C(X,Y): link cost from node x to y; = ∞ if not direct neighbors
- D(V): current value of cost of path from source to dest. v
- p(v): predecessor node along path from source to
- N': set of nodes whose least cost path definitively known

Dijsktra's Algorithm

1 *Initialization:*

```
2 N' = \{u\}
```

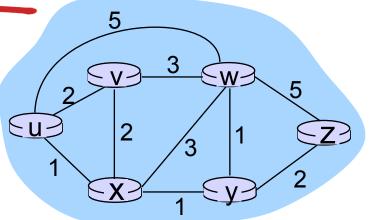

- 3 for all nodes v
- 4 if v adjacent to u
- 5 then D(v) = c(u,v)
- 6 else $D(v) = \infty$

7

8 Loop

???

until all nodes in N'

Dijsktra's Algorithm

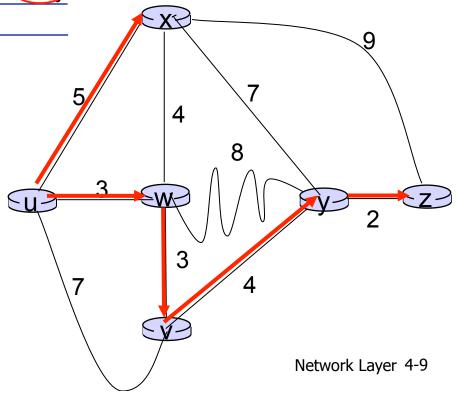

```
Initialization:
   N' = \{u\}
   for all nodes v
    if v adjacent to u
       then D(v) = c(u,v)
     else D(v) = \infty
6
   Loop
    find w not in N' such that D(w) is a minimum
    add w to N'
    update D(v) for all v adjacent to w and not in N':
12
       D(v) = \min(D(v), D(w) + c(w,v))
13
   /* new cost to v is either old cost to v or known
14
    shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

Dijkstra's algorithm: example

		D(v)	$D(\mathbf{w})$	D(x)	D(y)	D(z)
Step) N'	p(v)	p(w)	p(x)	p(y)	p(z)
0	U	7,u	3,u	5,u	∞	∞
1	uw	6,w		5,u) 11,W	∞
2	uwx	6,w)		11,W	14,X
3	uwxv				10,	14,X
4	uwxvy					12,
5	uwxvyz					

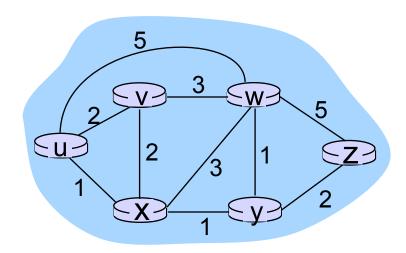

notes:

- construct shortest path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

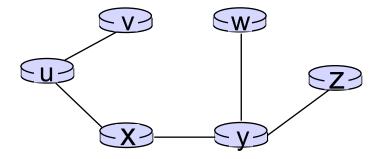

Dijkstra's algorithm: another example

Ste	р	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
	0	u	2,u	5,u	1,u	∞	∞
	1	ux ←	2,u	4,x		2,x	∞
	2	uxy <mark>∙</mark>	2,u	3,y			4,y
	3	uxyv 🕌		3,y			4,y
	4	uxyvw 🗲					4,y
	5	uxyvwz 🗲					

Dijkstra's algorithm: example (2)

resulting shortest-path tree from u:

resulting forwarding table in u:

destination	link
V	(u,v)
X	(u,x)
У	(u,x)
W	(u,x)
Z	(u,x)

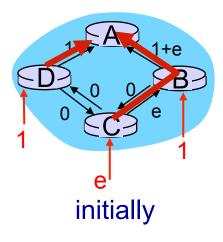

Dijkstra's algorithm, discussion

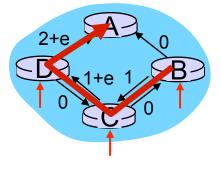

algorithm complexity: n nodes

- * each iteration: need to check all nodes, w, not in N
- \bullet n(n+1)/2 comparisons: O(n²)
- more efficient implementations possible: O(nlogn)

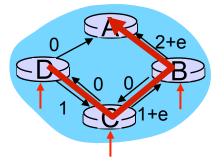

oscillations possible:

• e.g., support link cost equals amount of carried traffic:

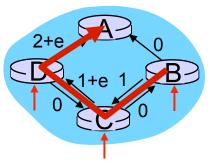

given these costs, find new routing.... resulting in new costs

given these costs, find new routing.... resulting in new costs

given these costs, find new routing.... resulting in new costs

4. Internet Routing: Outline

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

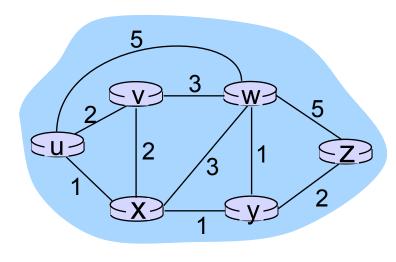

4.6 routing in the Internet

- RIP
- OSPF
- BGP

Bellman-Ford equation (dynamic programming)

```
let d_x(y) := \text{cost of least-cost path from } x \text{ to } y
then d_x(y) = \min_{v} \{c(x,v) + d_v(y)\}
cost \text{ from neighbor } v \text{ to destination } y
cost \text{ to neighbor } v \text{ to neighbor } v \text{ to destination } y \text{
```

Bellman-Ford example

clearly,
$$d_v(z) = 5$$
, $d_x(z) = 3$, $d_w(z) = 3$

B-F equation says:

$$d_{u}(z) = \min \{ c(u,v) + d_{v}(z), \\ c(u,x) + d_{x}(z), \\ c(u,w) + d_{w}(z) \}$$

$$= \min \{ 2 + 5, \\ 1 + 3, \\ 5 + 3 \} = 4$$

node achieving minimum is next hop in shortest path, used in forwarding table

- $D_{x}(y) = estimate of least cost from x to y$
 - x maintains distance vector $\mathbf{D}_{x} = [\mathbf{D}_{x}(y): y \in \mathbb{N}]$
- node x:
 - knows cost to each neighbor v: c(x,v)
 - maintains its neighbors' distance vectors. For each neighbor v, x maintains

$$\mathbf{D}_{v} = [D_{v}(y): y \in \mathbb{N}]$$

key idea:

- from time-to-time, each node sends its own distance vector estimate to neighbors
- when x receives new DV estimate from neighbor, it updates its own DV using B-F equation:

$$D_x(y) \leftarrow \min_{v} \{c(x,v) + D_v(y)\}$$
 for each node $y \in N$

* under minor, natural conditions, the estimate $D_x(y)$ converge to the actual least cost $d_x(y)$

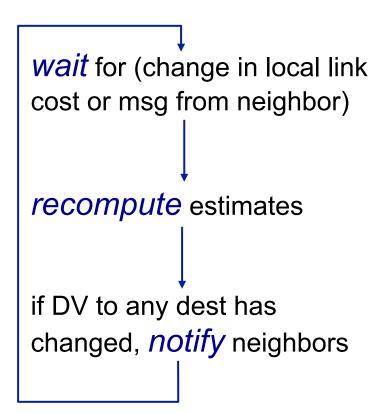

iterative, asynchronous: each local iteration caused by:

- local link cost change
- DV update message from neighbor

distributed:

- each node notifies neighbors only when its DV changes
 - neighbors then notify their neighbors if necessary

each node:

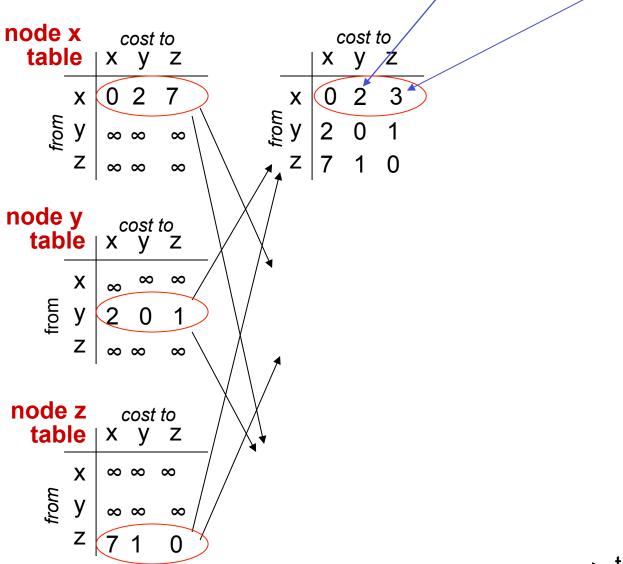

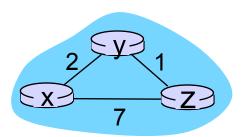

$$D_x(y) = min\{c(x,y) + D_y(y), c(x,z) + D_z(y)\}$$

= $min\{2+0, 7+1\} = 2$

$$D_x(z) = \min\{c(x,y) + D_y(z), c(x,z) + D_z(z)\}$$

= min{2+1, 7+0} = 3

$$D_{x}(y) = \min\{c(x,y) + D_{y}(y), c(x,z) + D_{z}(y)\}$$

$$= \min\{2+0, 7+1\} = 2$$

$$D_{x}(z) = \min\{c(x,y) + D_{y}(z), c(x,z) + D_{z}(z)\}$$

$$= \min\{2+1, 7+0\} = 3$$

$$D_{x}(z) = \min\{c(x,y) + D_{y}(z), c(x,z) + D_{z}(z)\}$$

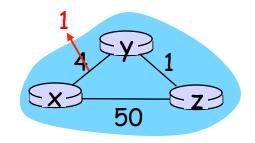

$$= \min\{2+1, 7+0\} = 3$$

$$\begin{bmatrix} cost \ to \\ cost \ to \ cost \ to \\ cost \ to \ cost \ to \\ cost \ to \ cost \ to \\$$

Distance vector: link cost changes

link cost changes:

- node detects local link cost change
- updates routing info, recalculates distance vector
- if DV changes, notify neighbors

"good news travels fast" t_0 : y detects link-cost change, updates its DV, informs its neighbors.

 t_1 : z receives update from y, updates its table, computes new least cost to x, sends its neighbors its DV.

*t*₂: *y* receives *z*'s update, updates its distance table. *y*'s least costs do *not* change, so *y* does *not* send a message to *z*.

Distance vector: link cost changes

link cost changes:

- node detects local link cost change
- bad news travels slow "count to infinity" problem!
- 44 iterations before algorithm stabilizes!

poisoned reverse:

- If Z routes through Y to get to X:
 - Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z)
- will this completely solve count to infinity problem?

Comparison of LS and DV algorithms

message complexity

- LS: with n nodes, E links, O(nE) msgs sent
- DV: exchange between neighbors only
 - convergence time varies

speed of convergence

- LS: O(n²) algorithm requires
 O(nE) msgs
 - may have oscillations
- DV: convergence time varies
 - may be routing loops
 - count-to-infinity problem

robustness: what happens if router malfunctions?

LS:

- node can advertise incorrect link cost
- each node computes only its own table

DV:

- DV node can advertise incorrect path cost
- each node's table used by others
 - error propagate thru network

4. Internet Routing: Outline

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP

Hierarchical routing

our routing study thus far - idealization

- all routers identical
- network "flat"
- ... not true in practice

scale: with 600 million destinations:

- can't store all dest's in routing tables!
- routing table exchange would swamp links!

administrative autonomy

- internet = network of networks
- each network admin may want to control routing in its own network

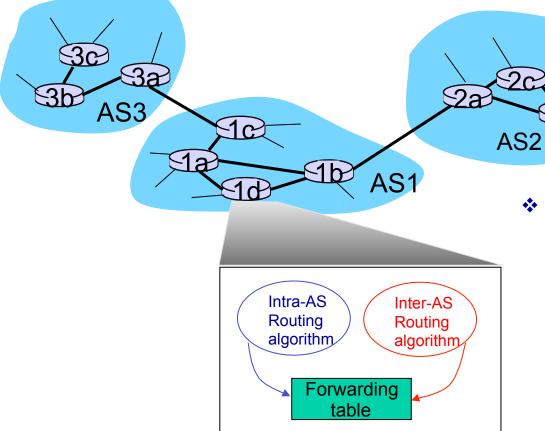

Hierarchical routing

- aggregate routers into regions, "autonomous systems" (AS)
- routers in same AS run same routing protocol
 - "intra-AS" routing protocol
 - routers in different AS can run different intra-AS routing protocol

gateway router:

- at "edge" of its own AS
- has link to router in another AS

Interconnected ASes

- forwarding table configured by both intraand inter-AS routing algorithm
 - intra-AS sets entries for internal dests
 - inter-AS & intra-AS sets entries for external dests

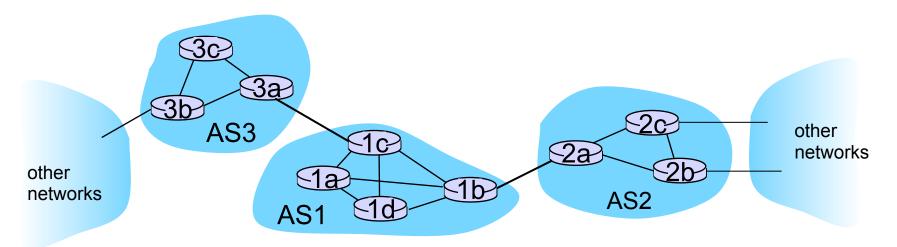

Inter-AS tasks

- suppose router in ASI receives datagram destined outside of ASI:
 - router should forward packet to gateway router, but which one?

ASI must:

- learn which dests are reachable through AS2, which through AS3
- propagate this reachability info to all routers in ASI

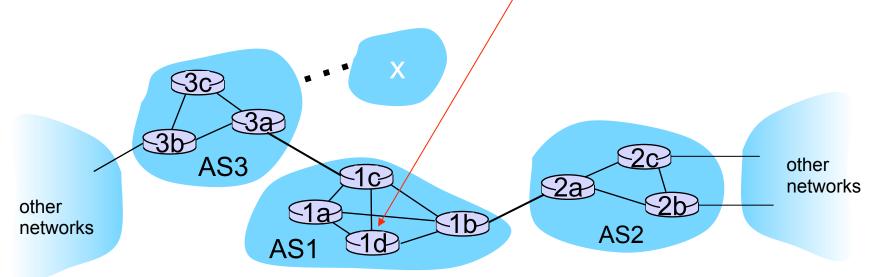

job of inter-AS routing!

Example: setting forwarding table in router 1d

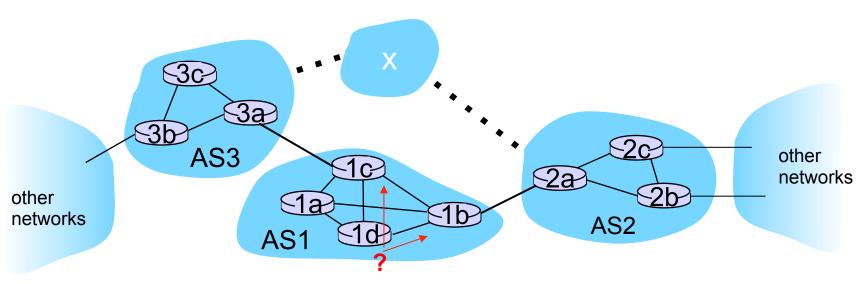

- suppose ASI learns (via inter-AS protocol) that subnet x reachable via AS3 (gateway Ic), but not via AS2
 - inter-AS protocol propagates reachability info to all internal routers
- router Id determines from intra-AS routing info that its interface I is on the least cost path to Ic

• installs forwarding table entry (x,l)

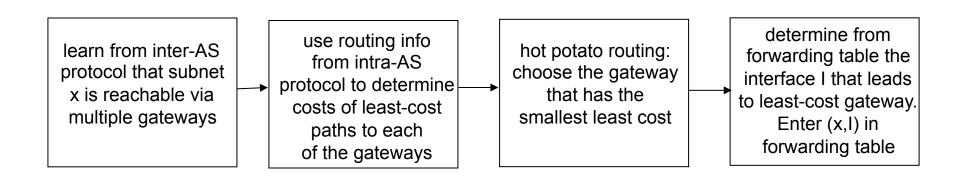

Example: choosing among multiple ASes

- now suppose ASI learns from inter-AS protocol that subnet
 x is reachable from AS3 and from AS2.
- to configure forwarding table, router 1d must determine which gateway it should forward packets towards for dest x
 - this is also job of inter-AS routing protocol!

Example: choosing among multiple ASes

- now suppose ASI learns from inter-AS protocol that subnet
 x is reachable from AS3 and from AS2.
- to configure forwarding table, router 1d must determine towards which gateway it should forward packets for dest x
 - this is also job of inter-AS routing protocol!
- hot potato routing: send packet towards closest of two routers.

4. Internet Routing: Outline

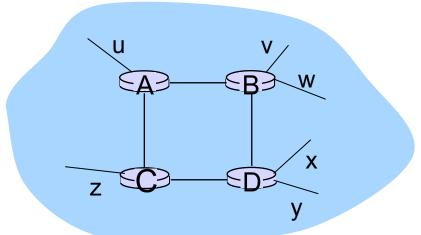

- 4.5 routing algorithms
 - link state
 - distance vector
 - hierarchical routing
- 4.6 routing in the Internet
 - RIP
 - OSPF
 - BGP

Intra-AS Routing

- also known as interior gateway protocols (IGP)
- most common intra-AS routing protocols:
 - RIP: Routing Information Protocol
 - OSPF: Open Shortest Path First
 - IGRP: Interior Gateway Routing Protocol (Cisco proprietary)

RIP (Routing Information Protocol)

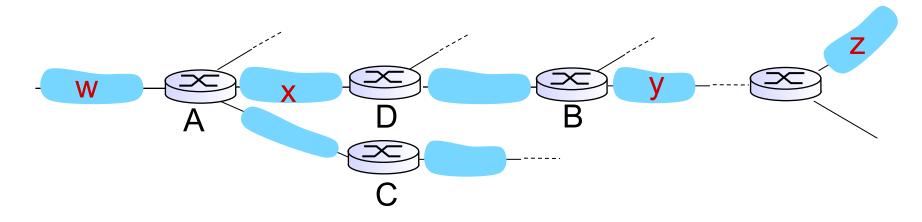

- included in BSD-UNIX distribution in 1982
- distance vector algorithm
 - distance metric: # hops (max = 15 hops), each link has cost I
 - DVs exchanged with neighbors every 30 sec in response message (aka advertisement)
 - each advertisement: list of up to 25 destination subnets (in IP addressing sense)

from router A to destination subnets:

<u>subnet</u>	<u>hops</u>
u	1
V	2
W	2
X	3
у	3
Z	2

RIP: example

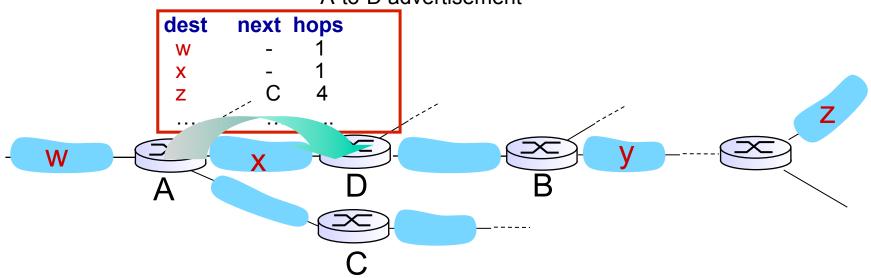

routing table in router D

destination subnet	next router	# hops to dest
W	Α	2
у	В	2
Z	В	7
X		1

RIP: example

A-to-D advertisement

routing table in router D

destination subnet	next router	# hops to dest
W	Α	2
У	В	2 5
Z	BA	7
X		1

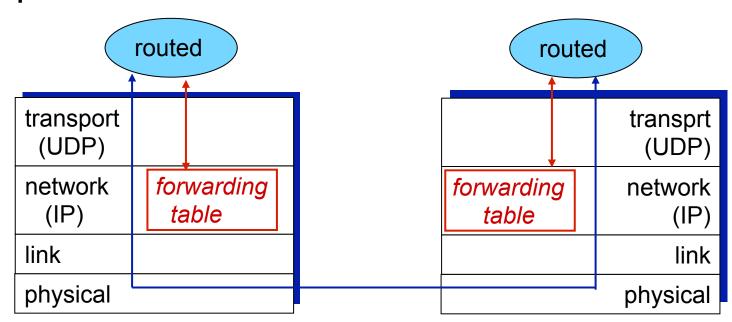

RIP: link failure, recovery

if no advertisement heard after 180 sec --> neighbor/ link declared dead

- routes via neighbor invalidated
- new advertisements sent to neighbors
- neighbors in turn send out new advertisements (if tables changed)
- link failure info quickly (?) propagates to entire net
- poison reverse used to prevent ping-pong loops (infinite distance = 16 hops)

RIP table processing

- RIP routing tables managed by application-level process called route-d (daemon)
- advertisements sent in UDP packets, periodically repeated

EIGRP enhancements to the DV algorithm

Split-horizon

 In routing updates sent out interface X, do not include routing information about routes that refer to interface X as the outgoing interface

Route poisoning

 Advertize a failed route with a metric value of "infinity". (16 in the case of RIP)

Poison reverse

 When learning of a failed route, suspend split-horizon rule for that route, and advertise a poisoned route.

Triggered update

When a route fails, send an update immediately.

* Holddown Process & Timer:

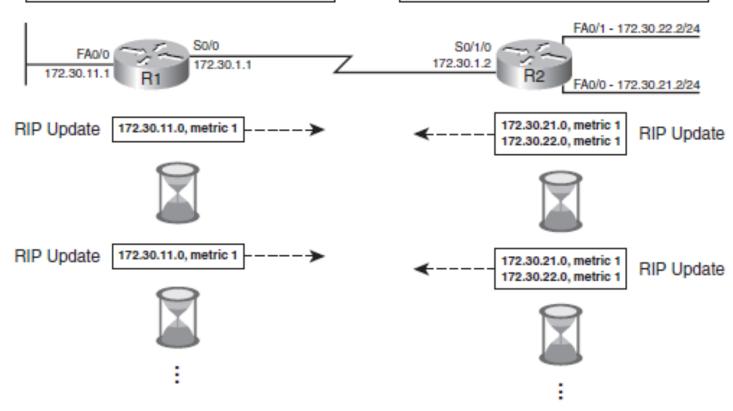

Example: Stable Network

R1 IP Routing Table

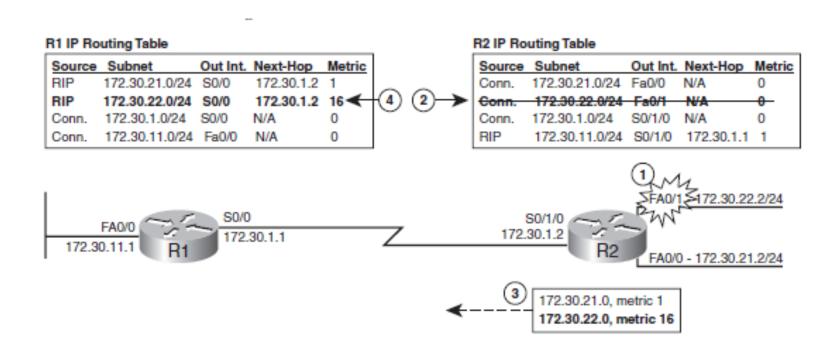

Source	Subnet	Out Int.	Next-Hop	Metric
RIP	172.30.21.0/24	So/o	172.30.1.2	1
RIP	172.30.22.0/24	So/o	172.30.1.2	1
	172.30.1.0/24		N/A	0
Conn.	172.30.11.0/24	Fa0/0	N/A	0

R2 IP Routing Table

Source	Subnet	Out Int.	Next-Hop	Metric
Conn.	172.30.21.0/24	Fa0/0	N/A	0
Conn.	172.30.22.0/24	Fa0/1	N/A	0
Conn.	172.30.1.0/24	S0/1/0	N/A	0
RIP	Subnet 172.30.21.0/24 172.30.22.0/24 172.30.1.0/24 172.30.11.0/24	S0/1/0	172.30.1.1	1

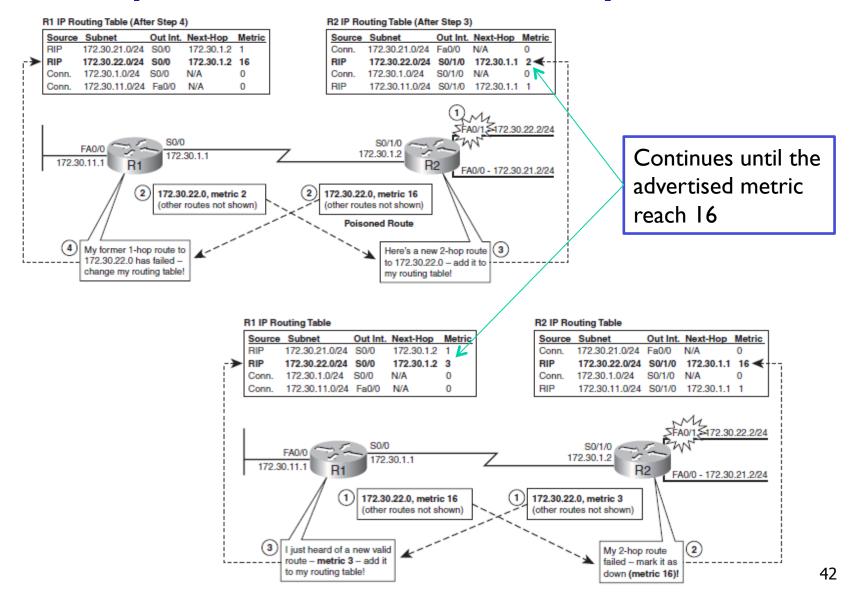

Example: Route Poisoning

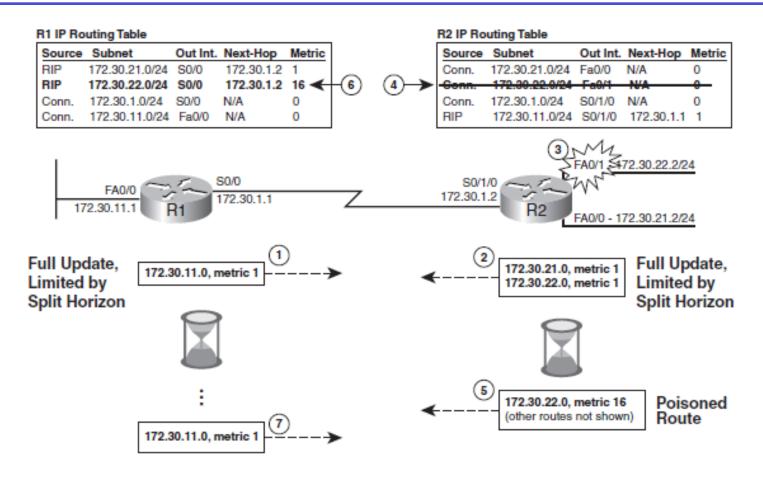

Advertize a failed route with a metric value of "infinity". (16 in the case of RIP)

Example: Count-to-infinity

Example: Split Horizon

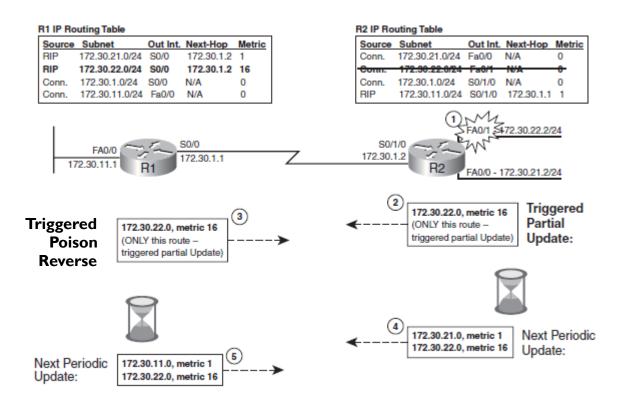

In routing updates sent out interface X, do not include routing information about routes that refer to interface X as the outgoing interface

Example: Poison Reverse & Triggered Update

Poison Reverse: When learning of a failed route, suspend split-horizon rule for that route, and advertise a poisoned route.

Triggered Updates: When a route fails, send an update immediately.

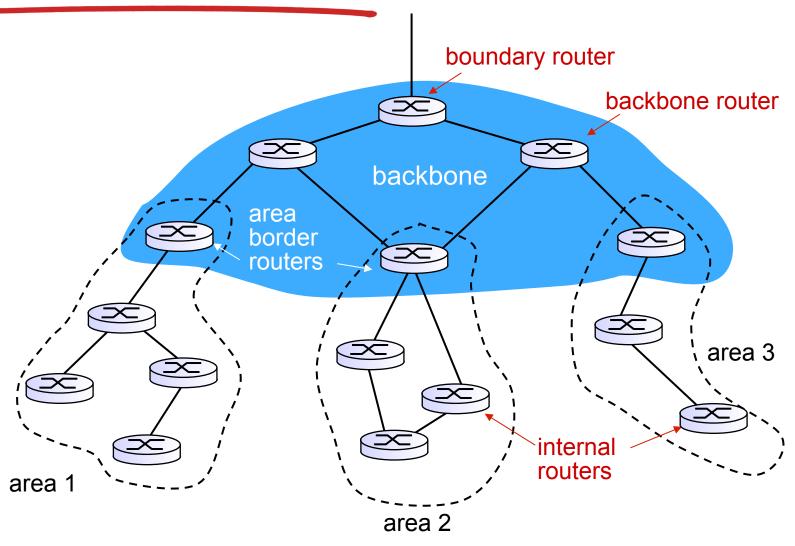

OSPF (Open Shortest Path First)

- "open": publicly available
- uses link state algorithm
 - LS packet dissemination
 - topology map at each node
 - route computation using Dijkstra's algorithm
- OSPF advertisement carries one entry per neighbor
- advertisements flooded to entire AS
 - carried in OSPF messages directly over IP (rather than TCP or UDP
- IS-IS routing protocol: nearly identical to OSPF

OSPF "advanced" features (not in RIP)

- security: all OSPF messages authenticated (to prevent malicious intrusion)
- multiple same-cost paths allowed (only one path in RIP)
- for each link, multiple cost metrics for different TOS (e.g., satellite link cost set "low" for best effort ToS; high for real time ToS)
- integrated uni- and multicast support:
 - Multicast OSPF (MOSPF) uses same topology data base as OSPF
- hierarchical OSPF in large domains.

Hierarchical OSPF

Hierarchical OSPF

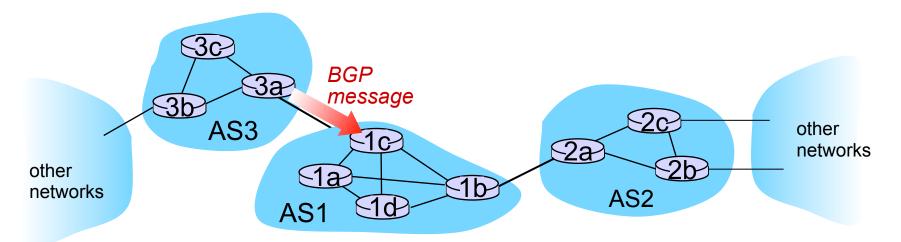

- * two-level hierarchy: local area, backbone.
 - link-state advertisements only in area
 - each nodes has detailed area topology; only know direction (shortest path) to nets in other areas.
- * area border routers: "summarize" distances to nets in own area, advertise to other Area Border routers.
- backbone routers: run OSPF routing limited to backbone.
- boundary routers: connect to other AS's.

Internet inter-AS routing: BGP

- * BGP (Border Gateway Protocol): the de facto inter-domain routing protocol
 - "glue that holds the Internet together"
- BGP provides each AS a means to:
 - eBGP: obtain subnet reachability information from neighboring ASs.
 - iBGP: propagate reachability information to all ASinternal routers.
 - determine "good" routes to other networks based on reachability information and policy.
- allows subnet to advertise its existence to rest of Internet: "I am here"

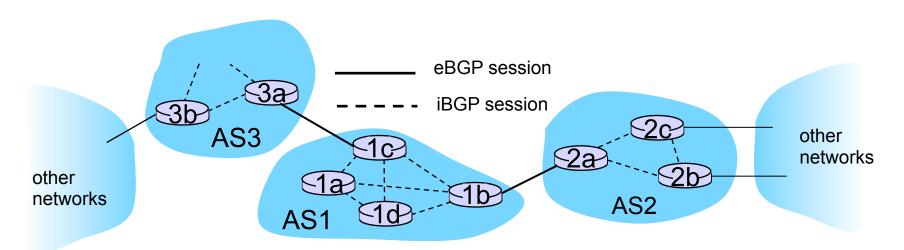

BGP basics

- BGP session: two BGP routers ("peers") exchange BGP messages:
 - advertising paths to destination prefixes ("path vector" protocol)
 - exchanged over semi-permanent TCP connections
- when AS3 advertises a prefix to ASI:
 - AS3 promises it will forward datagrams towards that prefix
 - AS3 can aggregate prefixes in its advertisement

BGP basics: distributing path information

- using eBGP session between 3a and 1c, AS3 sends prefix reachability info to AS1.
 - Ic can then use iBGP do distribute new prefix info to all routers in ASI
 - Ib can then re-advertise new reachability info to AS2 over Ibto-2a eBGP session
- when router learns of new prefix, it creates entry for prefix in its forwarding table.

Path attributes and BGP routes

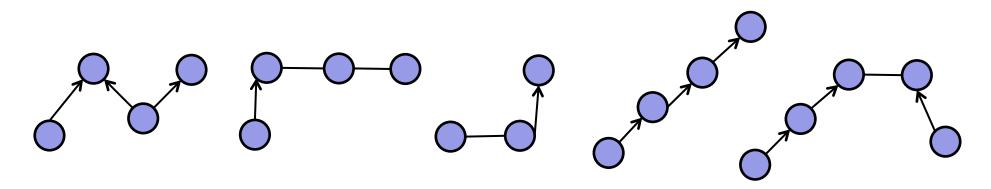

- advertised prefix includes BGP attributes
 - prefix + attributes = "route"
- two important attributes:
 - AS-PATH: contains ASs through which prefix advertisement has passed: e.g., AS 67, AS 17
 - NEXT-HOP: indicates specific internal-AS router to next-hop AS. (may be multiple links from current AS to next-hop-AS)
- gateway router receiving route advertisement uses import policy to accept/decline
 - e.g., never route through AS x
 - policy-based routing

BGP route selection (import policy)

- router may learn about more than I route to destination AS, selects route based on:
 - I. local preference value attribute: policy decision
 - 2. shortest AS-PATH
 - 3. closest NEXT-HOP router: hot potato routing
 - 4. additional criteria

BGP re-announce (export policy)

- Routers commonly use "valley-free" routing export policy
 - Never advertise peer or provider routes to another peer or provider.
- ❖ Examples (arrows indicate \$ flow or customer → provider relationship, else peering):

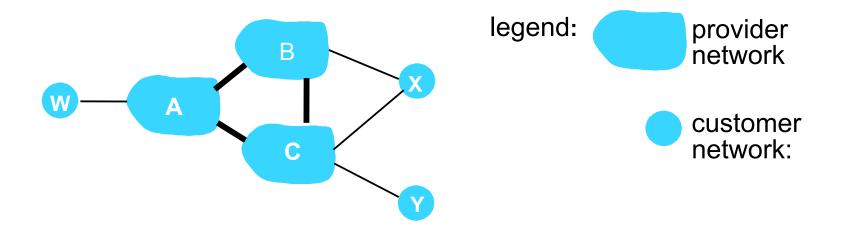

Q: Which of the above routes are permitted by "valley free" export policy?

BGP messages

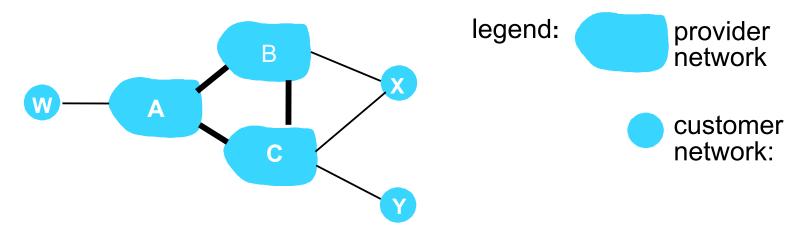

- BGP messages exchanged between peers over TCP connection
- BGP messages:
 - OPEN: opens TCP connection to peer and authenticates sender
 - UPDATE: advertises new path (or withdraws old)
 - KEEPALIVE: keeps connection alive in absence of UPDATES; also ACKs OPEN request
 - NOTIFICATION: reports errors in previous msg; also used to close connection

BGP routing policy

- A,B,C are provider networks
- X,W,Y are customer (of provider networks)
- * X is dual-homed: attached to two networks
 - X does not want to route from B via X to C
 - .. so X will not advertise to B a route to C

BGP routing policy (2)

- A advertises path AW to B
- B advertises path BAW to X
- Should B advertise path BAW to C?
 - No way! B gets no "revenue" for routing CBAW since neither W nor C are B's customers
 - B wants to force C to route to w via A
 - B wants to route only to/from its customers!

Why different Intra-, Inter-AS routing?

policy:

- inter-AS: admin wants control over how its traffic routed, who routes through its net.
- intra-AS: single admin, so no policy decisions needed scale:
- hierarchical routing saves table size, reduced update traffic

performance:

- intra-AS: can focus on performance
- inter-AS: policy may dominate over performance
